

M cyberMole

Better your own mole gets in first.

A local security assistant for small companies.

exposed to attack

01 / problem

Small companies keep big secrets. Nobody guards the door.

- late September 2026

Breach at Fakturownia

An invoicing service used by more than 600,000 Polish companies. Who invoices whom, for how much and to which account may now be in criminals' hands.

Next: a perfect fake invoice with a swapped account number.

[therecord.media](#) • [cert.orange.pl](#) • [money.pl](#)

01

No IT person and no security team

02

Admin accounts without two-step login

03

Invoices paid straight from email

02 / the gap

Security tools are built for IT teams. Small companies don't have one.

penetration test

Experts, weeks, a report

Expensive, one-off, and written in a language the owner does not speak.

× too costly for a 10-person company

antivirus

Guards single files

Catches known malware on one computer. It does not see the path from the internet to the client files.

× no idea what to fix first

cyberMole

Shows the path and the first move

Minutes, on the company's own computer, in plain language. Closes the most dangerous path first, then guides the team when something happens.

✓ built for people without IT

03 / solution

Your own mole breaks in first. On paper, on your computer.

flagship

Attack simulation

Maps the company and finds every path from the internet to client data, money or a stopped business. Picks the change that closes the most of them.

every day

Mail mole

Checks suspicious email before a person acts on it: lookalike domains, swapped account numbers, booby-trapped attachments.

when it happens

Incident mode

A few questions, then a plan with tasks for named people, a 72-hour clock for the data protection authority and lessons for next time.

0 B sent outside the company | local language model (Bielik 4.5B) | works offline

04 / attack simulation

Five ways in. One move closes two.

- 01 Describe the company: people, devices, vendors, what is already protected.
- 02 The engine chains techniques into tunnels: internet → foothold → crown jewels.
- 03 A planner picks the change that closes the most tunnels for the least effort.
- 04 You get the path, the fix and the cost: 15 minutes, free.

5 open tunnels

05 / mail mole

Looks like an invoice. It's a scam.

- 01 **Rules first:** a verdict in milliseconds, every signal quoted from the message.
- 02 **The local model explains it** in plain words to the person who received it.
- 03 **The model can raise the alarm**, never lower it.
- 04 **Gmail stays untouched:** read-only access, nothing sent, moved or marked.

06 / incident mode

Something happened. Everyone knows what to do.

- 01 **Five playbooks:** fake invoice, ransomware, lost laptop, account takeover, outage.
- 02 **Tasks for real people** in the company, in the right order.
- 03 **A 72-hour clock** for reporting a breach of personal data (GDPR).
- 04 **Works offline**, even when the network is down.

M Nowak Law Office

DashboardTunnelsMail moleIncidentlocal

Stop. Check. Act.
Suspicious invoice · first steps

1

Grace (accounting) · now

Stop payments to new account numbers
No payment to an account number sent by email goes out until someone confirms it by phone.

2

Grace (accounting) · now

Call the vendor on the number from the contract
Not on the number from the email. Ask whether they really changed their account.

3

Everyone · now

Do not delete the email, it is evidence
The mole saved a copy with headers. The bank, the police and CERT will need it.

The vendor's number from the contract, not from the suspicious email.

How do you trust a mole that **attacks**?

It simulates, it **does not** **hack**

The engine reasons over the company's own description. It never breaks into any system.

Read-only

The mailbox is opened read-only. Nothing is sent, deleted or marked as read.

Local

The language model runs on the company's computer. Client data never leaves it.

Authorized and visible

The company starts every test itself and sees the mole on screen: "authorized test".

computer

authorized test

08 / market

Small companies first. Then up the supply chain.

Attackers use small companies as a way into bigger ones. One invoicing service exposed 600,000 others. We climb the same ladder, from the bottom.

now

Companies of 2 to 20 people

Law firms, accounting offices, clinics, small shops. Client data, no IT.

next

Their suppliers and partners

The same playbooks for whole chains of companies that invoice each other.

later

Mid-size companies

Teams with IT but the same blind spots: paths, priorities, procedures.

Working today. Ready for the first companies.

done

- ✓ Attack-path engine with tunnels to data, money and downtime
- ✓ Mail mole: rule engine plus local model explanations
- ✓ Five incident playbooks with tasks and a 72-hour clock
- ✓ Own-company setup and Gmail over read-only IMAP
- ✓ 53 automated tests, no cloud needed

goal

- Pilots with real small companies
- One-click installer for Windows and macOS
- Checks of the real environment: router, Microsoft 365
- A security assistant every small company can afford
